RE: Edwards Aquifer Protection Program 2019 Comments

Dear Ms. Ruthstrom,

The following comments are submitted on behalf of the member organizations of the Greater Edwards Aquifer Alliance (GEAA), all of which are united behind a comprehensive plan to protect the Edwards Aquifer, its springs and watersheds, and the Texas Hill Country. The memberships of these organizations represent a large segment of the population that relies on the Edwards Aquifer for their potable water supply, and a broad consensus on how to best protect the aquifer.

We first ask that each member group of our Alliance, all of which have endorsed these recommendations, be listed individually as submitting these comments. Please do not list them collectively as the Greater Edwards Aquifer Alliance. Provided here is a list of the member groups that belong to GEAA for inclusion as supporting these comments.

Unprecedented growth in the Texas Hill Country has boosted disposal of sewage effluent to the forefront of issues of concern among our members. Encouraging land application and the beneficial reuse of this effluent enhances efforts to conserve water and more effectively preserves the quality of recharge to our ground and surface waters. We therefore wholeheartedly support the proposed rule-making to allow beneficial reuse to partially substitute for Texas Land Application Permit (TLAP) wastewater disposal area.

We respectfully request that TCEQ conduct a stakeholder process to review current science and discuss potential EAPP rule and guidance document modifications in a collaborative setting. Such a conversation would not only provide an opportunity for stakeholders to efficiently coordinate and reduce duplication of efforts, but also provide TCEQ with the best available information to inform EAPP improvements. We believe that such a stakeholder process is consistent with the TCEQ philosophy to base decisions on sound science, ensure regulations are effective and current, and ensure meaningful public participation in the decision-making process.

Additional, specific comments on the Edwards Rules are attached for your consideration, including recommendations submitted in 2005 and subsequent years. Also included is a 1997 paper "Protecting the Edwards Aquifer, A Scientific Consensus," which was endorsed by 39 scientists, engineers, and planners. We ask that you consider and act on this scientific consensus, and the recommended measures embodied therein, as you go about amending the Edwards Rules. Thank you for your consideration of these comments. If you have any questions, please contact me at your convenience at 210-320-6294 or Annalisa@AquiferAlliance.org.

Sincerely,

Annalisa Peace, Executive Director

• **Regulation of aggregate production operations (APOs) located over the Edwards Aquifer**

The creation of a draft Best Management Practices (BMP) for aggregate production operations impacting the Edwards Aquifer is long overdue. Soliciting public input is appreciated by those of us who are interested in preventing pollution of the Edwards Aquifer from APO's.

TCEQ should also consider incorporating Edwards-specific rules for quarries and rock crushers in the Recharge and Contributing Zones. Where these facilities are located in Edwards Limestone, the underlying aquifer is particularly vulnerable to contamination, whether or not the quarry actually excavates to below the aquifer water level. Without more stringent TCEQ regulations, quarries and rock crushers threaten to degrade the Aquifer and damage the health and water supply of adjacent communities.

TCEQ should provide additional venues for public participation in considering APO's on the Edwards Aquifer Recharge Zone (EARZ) by providing for public meetings, public hearings and contested case hearing process for water pollution abatement. This could be achieved by changing the Water Pollution Abatement Plan (WPAP) to a Water Pollution Abatement Permit. Since APO's are only required to go through the permit application process for air quality, the public is deprived of the opportunity to pursue concerns regarding vital groundwater resources.

Allowing aggregate mining to an estimated depth of only twenty-five feet over the Edwards Aquifer Recharge Zone is an unsafe practice. Mining depth should be raised to at least fifty feet over the Edwards Aquifer in order to avoid pollution. Edwards Aquifer pollution can potentially occur at any time during the operation of a quarry, as well as at any given time after the quarry pit site is abandoned. The use of a well for mining depth information in the quarry pit area can be unreliable and inaccurate. Currently, determining where the placement of a well should be in relation to the quarry pit is not defined. Aggregate quarries can be very large. For example, two quarries in Medina County were proposed to be one mile wide and three miles in length. If wells are to be used to accurately determine the safe depth of quarrying, they must be in close proximity to the active mining area. In large quarries, it may be necessary to have multiple monitoring wells to accurately determine the safe depth of mining permitted. Data obtained from these wells should be monitored closely to determine the water level in order to ensure that pollution of the aquifer does not occur due to excessive removal of limestone, especially after periods of heavy rainfall over the underlying quarry pit.

Sensitive features identified in geologic assessment: Currently, TCEQ permits the practice of allowing residue derived from settling ponds during the aggregate processing and allowing this material to be returned to the quarry pit, where it is dumped. This practice should be prohibited on the EARZ. No analysis of this material is currently required, yet it contains potential pollutants including surfactants. Allowing this material to be placed back into the recharge zone, where it can leach back into the aquifer not only exposes the Aquifer to pollution, but also creates an impervious cover for the floor of the quarry pit. If TCEQ allows the continued disposal of this grout-like material to be dumped into the quarrying pit, the aggregate company should be required to provide an alternative to make up for the loss of recharge to the aquifer, as is noted when it is determined that a sensitive feature must be sealed.

A major problem with the present regulations is that there is no requirement for any land reclamation and/or revegetation upon quarry abandonment. There is also no provision for maintenance of any berms or other pollution controls that were installed by the quarry operator.

Furthermore, the technical guidance on BMP for quarrying operations should not solely apply to the EARZ, but should be utilized in other karst aquifers, particularly in areas where both the Contributing Zone of the Edwards Aquifer overlaps the recharge zone of other aquifers. Given that recent studies identify communication between

the Trinity and the Edwards karst aquifer systems, it does not seem to be prudent that this manual should apply only to the Edwards Aquifer.

Pollution of the Edwards Aquifer or other karst aquifers can still occur if aggregate companies are not closely monitored on a regular basis. Violators should be subjected to substantial, strictly enforced fines and cleanup costs.

Revisions to the Edwards Aquifer Protection Program technical guidance manual, RG-348, including the method for calculating removal of total suspended solids

There is a growing national consensus that drainage problems produced by urban development, such as downstream scour and habitat damage as well as flooding, can best be addressed by incorporating low impact development (LID) practices in new development and retrofit projects. The basic goal of LID is to make site runoff conditions after development mimic the pre-development condition. This is accomplished by using a substantial toolbox of measures, many of which involve promoting infiltration and evapotranspiration in some areas to compensate for the effects of impervious cover in development. However, in the Edwards Aquifer area this can be very difficult to achieve when many BMPs incorporate liner requirements.

The Edwards Rules do not prohibit the infiltration of stormwater and 30 TAC Chapter 331 implies that it is appropriate in some situations when it states that “improved sinkholes or caves located in karst topographic areas that inject storm water, flood water, or groundwater may be authorized.” A primary question then is “What must be the quality of stormwater for ‘injection’ (or infiltration) to be authorized?” While obvious, it is nevertheless worthwhile to note that “natural” infiltration to the Edwards Aquifer includes runoff through dirt, animal droppings, and a wide range of other organic matter. Expectations for infiltration purity in developed areas need to be based on a realistic and balanced assessment of significant pollution risk.

Permanent BMPs revisions to promote LID and water conservation

1. Replace impermeable liner requirement with leaky liner that provides sufficient filtering for discharge. Suggested language (from retention/irrigation guidance): Liners should consist of a minimum of 12 inches of soil. Any geologic/sensitive features that could allow the water to directly enter the aquifer must be sealed prior to installing the liner. Rocky soils are acceptable for liners; however, the coarse material (diameter greater than 0.5 inches) should not account for more than 30% of the soil volume.
2. Require that underdrains be configured to provide internal water storage (IWS) as shown in Figure 1 for sand filters and bioretention (without the impermeable liner shown in that version). Reason – underdrains will likely be required because of low soil permeability, but IWS will increase recharge between events.
3. Eliminate filter fabric separating filtration media from gravel underdrain in bioretention systems and replace with a choker layer consisting of 2 inches of #8 or #89 stone. Reason – Allows plant roots access to the soil below the system to improve survivability in dry weather
4. Allow roof runoff to be used for direct aquifer recharge after sand filtration or biofiltration, if not comingled with other runoff from the site. Reason - Roof runoff is substantially cleaner than runoff associated with paved surfaces and enhanced recharge would offset groundwater demands associated with new development.

Temporary BMPs

Recent research (Eck et al. 2012) and experiences locally (e.g., City of Austin Water Treatment Plant 4) indicate that substantial improvement in discharge quality at construction sites can be achieved with the use of mulch on disturbed areas. Consequently, we recommend a new section specifically on mulch, which would require that all vegetation removed as part of land clearing activities be chipped/shredded on site and used to cover disturbed areas to the extent feasible.

- **Compliance monitoring of plan-related best management practices following installation.**

We have seen frequent examples of inadequate erosion and sedimentation construction controls causing significant pollution events. Off-channel ponds, rock gabions in addition to silt fences, and appropriately limited phasing of clearing and grading all need to be required and strictly enforced to protect the aquifer from construction runoff. Construction staging should also be minimized to allow for immediate revegetation and minimization of pollution risks. These requirements should all be strictly monitored and violations assessed significant penalties to act as a deterrent to non-compliance.

Improving and Facilitating use of Sustainable Development Stormwater Structural Control Measures within the Edwards Aquifer Recharge Zone

Stormwater management engineering best practices and scientific knowledge about regulated activities with the potential to pollute the Edwards Aquifer and hydrologically connected surface streams have advanced in recent years. For example, GEAA is very interested in discussing EAPP guidance regarding media composition and liner requirements for certain types of stormwater structural control measures. We have been awarded a grant for a stormwater retrofit and research project from the City of San Antonio's Proposition 1 Edwards Aquifer Protection Projects within the Urbanized Areas of Bexar Counties Recharge and Contributing Zone Program. Included in our funding agreement is pre and post construction stormwater monitoring data that will, we hope, be useful to this discussion.

Some specific improvements to the Texas Commission on Environmental Quality (TCEQ) Edwards Aquifer Protection Program (EAPP) and 30 Texas Administrative Code Chapter 213 (Edwards Rules) and associated guidance documents that would improve the level of protection provided to the aquifer include the following:

- **Technical guidance documentation for stormwater structural control measures (SCM) should be reviewed and updated to reflect current engineering science.** Design criteria for some SCM may be out dated. For example, TCEQ EAPP biofiltration media requirements include 20% compost, which City of Austin analysis has demonstrated may result in unintended nutrient export comprising the effectiveness of the SCM. Clarification of guidance documents regarding infiltration for certain SCM is also needed for consistency, and could occur in an administrative manner not requiring a rule revision. Additionally, liner requirements for infiltration SCM for some land uses less likely to generate highly contaminated runoff should be reviewed using the best available data to determine if regulatory requirements may be simplified such that additional recharge to the aquifer may be achieved without degrading the quality of recharge by an unacceptable amount.
 - Performance comparison of stormwater biofiltration designs <https://repositories.tdl.org/twdl-ir/handle/2152/10905>
 - Evaluation of potential for water quality impacts from unlined stormwater basins in the Barton Springs Recharge Zone http://www.austintexas.gov/watershed_protection/publications/document.cfm?id=240241
- **The stormwater best management practice performance standard should be reviewed relative to the stated purpose of 30 TAC 213.1 to protect the Edwards Aquifer using the latest engineering and hydrogeologic data.** Substantial information on stormwater structural control measure performance has been generated by multiple entities including the City of Austin (see below for examples). Water quality temporal trend analysis for Edwards Aquifer spring, well and hydrologically-connected surface water resources has been generated by multiple entities (see below for examples), and indicates degradation over time for some constituents in Barton Springs. The 80% total suspended solids removal standard of the

Edwards Rules remains the benchmark used for assessing compliance for critical infrastructure projects like State Highway 45 Southwest. TCEQ, in a collaborative stakeholder process, should compile and review the latest available stormwater structural control measure performance information in comparison to water quality data from Edwards Aquifer springs, wells, and hydrologically-connected surface streams to ensure that existing regulations are effective in protecting the Edwards Aquifer.

Permitting Texas Pollutant Discharge Elimination System (TPDES) should be prohibited in the Contributing Zone of the Edwards Aquifer.

In addition to pollution from construction and urban runoff, sewage and wastewater effluent are among the primary pollutants of the Edwards Aquifer. Many of the sewage plants in the region use irrigation/land application for wastewater effluent disposal. The Edwards rules should be strengthened to include specific requirements for wastewater treatment, storage, and irrigation in the following ways:

- Increase storage required for subsurface irrigation systems to be equivalent to what is currently required for surface irrigation systems.
- Require effluent monitoring for total nitrogen and phosphorous
- Require automatic shut-off soil moisture monitoring using tensiometers
- Baseline sampling of adjacent creeks and quarterly sampling after rainfall during irrigation.
- Measure buffers from creek beds rather than stream center to ensure adequate creek protection as stream beds wash out from development.
- Adopt stricter standards for lift stations, similar to City of Austin standards.

There is widespread scientific consensus, and governmental support for, prohibiting wastewater discharges into the Edwards Aquifer in order to prevent degradation. TCEQ should amend the Edwards rules to prohibit any direct discharges of effluent in the Contributing and Transition Zones of the Edwards Aquifer.

Disposal of wastewater is one of the greatest threats to maintaining water quality in the contributing watersheds to the Edwards Aquifer. Current rules only prevent wastewater discharge within the Recharge Zone. Discharges in the Contributing Zone, even in compliance with current rule, would significantly alter the quality of these oligotrophic surface waters and degrade the aquifer, as demonstrated by recent analysis of a proposed discharge permit to Onion Creek. The quality of water in the Contributing Zone directly impacts the quality of discrete recharge in the Recharge Zone. Direct discharge of wastewater should be prohibited not only within the Recharge Zone, but also within the Contributing Zone of the San Antonio and Barton Springs segments of the Edwards Aquifer. Existing discharge permit procedures should be re-evaluated relative to 2006 U.S. Fish and Wildlife Service recommendations.

GEAA recommends that TCEQ should revise Section 213.6 regarding Wastewater Treatment and Disposal Systems, to prohibit TPDES permits from being approved within the Contributing Zone of the Edwards Aquifer. We believe that direct discharge of wastewater into waterways on the contributing zone is a growing problem that needs to be urgently addressed. Effluent discharges pose a risk to human health by introducing anthropogenic pharmaceuticals and other unmonitored chemicals into potable water supplies. Sensitive surface waters within the Contributing Zone cannot withstand the reductions in dissolved oxygen and increases in algae producing constituents that are caused by effluent discharge.

- Emerging contaminants: Current rules for the contributing zone do set minimum levels of effluent treatment for pollution control. However, anthropogenic contaminants only found in sewage effluent, such as unmetabolized pharmaceuticals and personal care products, are not regulated. The effects of allowing these contaminants to accumulate in groundwater which will be used for drinking water are unknown, and potentially dangerous. Many private well owners, local water supply companies, including San Antonio Water Systems that serves the entire City of San Antonio, do not pretreat Edwards Aquifer water prior to distribution and consumption.
- Rapid, dense residential development over the contributing zone: Three counties in the contributing zone, Comal, Hays, and Kendall, are among the ten fastest growing counties in the USA. Developers are building dense subdivisions and applying for TPDES permits. The growing number of wastewater treatment plants discharging directly into waterways on the Contributing Zone is cause for great concern.

Provide Additional Protection for the Edwards Aquifer Contributing Zone

GEAA urges TCEQ to adopt rules for the Edwards Aquifer Contributing Zone. According to recent studies¹ “Currently, Texas Commission on Environmental Quality (TCEQ) regulations on the Edwards Aquifer Contributing Zone are limited, especially when compared with those for the Edwards Aquifer Recharge Zone. The rules are predicated on the premise that no water from the Contributing Zone directly recharges the Edwards Aquifer and that the role of the Contributing Zone is solely to convey surface water to the Edwards Aquifer Recharge Zone where it can then enter the subsurface.

In reality, the Edwards Aquifer is significantly recharged by water infiltrating the Contributing Zone. This infiltrated water is then conveyed to the Edwards Aquifer from the Trinity Aquifer by interformational flow. Recent studies support the supposition that hydraulic communication between the upper Glen Rose Aquifer (i.e., the upper most

¹ Interconnection of the Trinity (Glen Rose) and Edwards Aquifers along the Balcones Fault Zone and Related Topics Karst Conservation Initiative, February 17, 2011, Meeting Proceedings - Austin, Texas, July

2011http://www.bseacd.org/uploads/AquiferScience/Proceedings_Edwards_Trinity_final.pdf

unit of the Trinity Aquifer) and the Edwards Aquifer is greater than previously believed. Because of this high level of hydraulic communication, the distinction between the Contributing Zone and the Recharge Zone of the Edwards Aquifer is not great, and in many localities, the Edwards Aquifer Contributing Zone effectively acts to recharge the Edwards Aquifer in a fashion indistinguishable to the Edwards Aquifer Recharge Zone.”

Please review existing staffing EAPP staffing levels to ensure sufficient staff are available to effectively achieve the stated purpose of the Edwards Rules. Water Pollution Abatement Plans are not consistently verified with proactive inspections in the field, and inspections occur only in response to complaints. However, greenfield developments may occur in areas not visible or accessible to the public, such that no complaints may be generated.

We also ask that TCEQ provide adequate funding for trained and experienced staff, and that monitoring and enforcement of the Edwards rules, where appropriate, be delegated to local agencies that are better equipped to handle these duties.

We are aware that TCEQ staff is under special pressure to process Water Pollution Abatement Plans for approval within 60 days rather than the 90 day period provided for in the Edwards Rules. If anything, the rules should increase the 90 day period to provide for more comprehensive review of WPAPs.

Additional Comments

As detailed in our 2005 comments and supported by the Scientific Consensus paper, our recommendations include requiring adequate buffer zones to protect streams, springs and recharge features, limits to impervious cover on the Edwards Recharge and Contributing zones, expanding the pollution reduction standards to include toxic metals, organic chemicals and nutrients, and other measures and strategies that we believe will be adequately protective of our water quality.

The Optional Water Quality Measures (appendices A and B of RG-348, EAPP Technical Guidance Manual) are not adequate to protect Endangered Species and allow unnecessary pollution of the Edwards Aquifer. The optional measures, among other deficiencies, fail to limit impervious cover, only monitor for one constituent (Total Suspended Solids), allow for increases in pollutant loads from developed properties, and allow for sealing of sensitive recharge features rather than preservation and setbacks.

There is widespread scientific consensus that limiting impervious cover in both the recharge and contributing zones is necessary to maintain water quality in the Edwards Aquifer.² Scientists agree that engineered controls, even when perfectly maintained, cannot replace impervious cover limits. TCEQ should recognize this sound science by implementing impervious cover limits of no more than 10% in the recharge zone and 15% in the contributing zone.

Where engineered water quality controls are used these should be inspected frequently with significant fines assessed for malfunctioning facilities. In general, the penalties for violations of the Edwards Rules seem low in relation to the severity of the violations and should be increased to act as a preventative deterrent.

Attached to this letter is a copy of our 2005 comments and the Scientific Consensus paper. The Greater Edwards Aquifer Alliance and the many groups who join us ask that you act now to adopt these recommendations into the TCEQ Edwards Rules.

² See *Protecting the Edwards Aquifer: A Scientific Consensus*, signed by 39 scientists, planners, and engineers in 1997, also available at <http://www.aquiferalliance.org>.
